Three screenshots: filtered and sorted catalog; cart with two products and changed quantity; checkout review with line items and total.

The final npm run check result, showing that it completed successfully.

A short explanation:

The sort choice is saved in a state variable in ProductsPage, so the page remembers what you picked. The page first filters the list by search and category, then it sorts a copy of that list. The original product data is never changed, so choosing Default brings back the normal order. The plus and minus buttons call the same update function as the number input, so there is only one set of rules. That rule already blocks zero and blocks going past the stock, so the buttons just follow it. The checkout page reads the cart and shows the name, quantity, and subtotal for each item. The review and the total come from the same cart, so they always match.
